

Abstract—The purpose of this study was to determine if there were differences in the prevalence of musculoskeletal disorders among different types of workers. The study included 600 male employees from three companies who had been employed for at least one year. Data were collected by means of a self-administered questionnaire. The results showed that the prevalence of musculoskeletal disorders was higher among non-manual workers than among manual workers. This finding suggests that the risk of developing musculoskeletal disorders is greater for non-manual workers than for manual workers.
